### Abstract

The selective two-electron reduction of O<sub>2</sub> by one-electron reductants such as decamethylferrocene (Fc<sup>\*</sup>) and octamethylferrocene (Me<sub>8</sub>Fc) is efficiently catalyzed by a binuclear Cu(II) complex ([Cu<sup>II</sup><sub>2</sub>(LO)(OH)]<sup>2+</sup> (**D1**) {LO is a binucleating ligand with copper-bridging phenolate moiety} in the presence of trifluoroacetic acid (HOTF) in acetone. The protonation of the hydroxide group of [Cu<sup>II</sup><sub>2</sub>(LO)(OH)]<sup>2+</sup> with HOTF to produce [Cu<sup>II</sup><sub>2</sub>(LO)(OTF)]<sup>2+</sup> (**D1-OTF**) makes it possible for this to be reduced by two equiv of Fc<sup>\*</sup> via a two-step electron transfer sequence. Reactions of the fully reduced complex [Cu<sup>I</sup><sub>2</sub>(LO)]<sup>+</sup> (**D3**) with O<sub>2</sub> in the presence of HOTF led to the low-temperature detection of the absorption spectra due to the peroxy complex ([Cu<sup>II</sup><sub>2</sub>(LO)(OO)]) (**D**) and the protonated hydroperoxy complex ([Cu<sup>II</sup><sub>2</sub>(LO)(OOH)]<sup>2+</sup> (**D4**)). No further Fc<sup>\*</sup> reduction of **D4** occurs, and it is instead further protonated by HOTF to yield H<sub>2</sub>O<sub>2</sub> accompanied by regeneration of [Cu<sup>II</sup><sub>2</sub>(LO)(OTF)]<sup>2+</sup> (**D1-OTF**) thus completing the catalytic cycle for the two-electron reduction of O<sub>2</sub> by Fc<sup>\*</sup>. Kinetic studies on the formation of Fc<sup>\*+</sup> under catalytic conditions as well as for separate examination of the electron transfer from Fc<sup>\*</sup> to **D1-OTF** reveal there are two important reaction pathways operating. One is a rate-determining second reduction of **D1-OTF**, thus electron transfer from Fc<sup>\*</sup> to a mixed-valent intermediate [Cu<sup>II</sup>Cu<sup>I</sup>(LO)]<sup>2+</sup> (**D2**) which leads to [Cu<sup>I</sup><sub>2</sub>(LO)]<sup>+</sup> which is coupled with O<sub>2</sub> binding to produce [Cu<sup>II</sup><sub>2</sub>(LO)(OO)]<sup>+</sup> (**D**). The other involves direct reaction of O<sub>2</sub> with the mixed-valent compound **D2** followed by rapid Fc<sup>\*</sup> reduction of a putative superoxo-dicopper(II) species thus formed, producing **D**.

### Introduction

Copper proteins which are involved in dioxygen (O<sub>2</sub>) processing<sup>1</sup> possess highly evolved active-site environments, thus optimized via ligation with appropriate atom type (e.g., N, O, S), ligand charge (e.g., RS- vs. RSR'), the number of donors and their juxtaposition, resulting steric factors and second coordination shell influences,<sup>2</sup> all leading to the generation of specific Cu<sub>n</sub>(O<sub>2</sub>) (n = typically 1–3) structures suitable for a particular function.<sup>1f,3</sup> The latter include O<sub>2</sub>-transport (Cu<sup>I</sup><sub>2</sub> + O<sub>2</sub> ⇌ Cu<sub>2</sub>(O<sub>2</sub>) and substrate oxygenation (R-H → R-OH).<sup>4</sup> Another major class are copper oxidases, those effecting

Supporting Information Available: Figures S1–S14. This material is available free of charge via the Internet at <http://pubs.acs.org>.

two-electron substrate oxidations (galactose oxidases;<sup>5</sup> amine oxidases)<sup>6</sup> while reducing O<sub>2</sub> to H<sub>2</sub>O<sub>2</sub>.<sup>7</sup> Meanwhile, multicopper oxidases (MCO's)<sup>1a,1c,8</sup> and heme-copper oxidases (HCO's)<sup>9</sup> facilitate 4e<sup>-</sup>/4H<sup>+</sup> reduction of dioxygen to water; the latter reactivity is analogously a fuel cell reaction.<sup>10–16</sup>

The ligand environment also defines the resulting chemistry for copper(I)-O<sub>2</sub> complexes, and dramatic tuning of O<sub>2</sub>-adduct structure and reactivity may come via a change in chelate ligand denticity. Tetradeinate nitrogen based ligands typically provide for  $\mu$ -1,2-peroxodicopper(II) adducts (**A**), tridentate chelates generally lead to side-on bound ( $\mu$ - $\eta^2$ :  $\eta^2$ )peroxo dicopper(II) complexes (**B**) and other tridentate or bidentate ligands support the formation of bis( $\mu$ -oxo)dicopper(III) Cu<sup>III</sup><sub>2</sub>(O)<sub>2</sub> complexes (**C**) (Scheme 1).<sup>1f,3</sup>

We recently became interested in examining discrete copper complexes as catalysts for 4e<sup>-</sup>/4H<sup>+</sup> O<sub>2</sub>-reduction to water.<sup>15,17</sup> There is considerable interest in such catalysis, not only to aid the elucidation of fundamental principles relevant to biological processes (as above), but also due to the technological significance such as in fuel cell applications.<sup>10–16,18</sup> In fact, we found that ligand-(di)copper complexes forming **A**, **B** or **C** (Scheme 1) can all catalyze the solution phase 4e<sup>-</sup>/4H<sup>+</sup> O<sub>2</sub>-reduction to water, employing ferrocenes reductants and acids as proton sources.<sup>17</sup> This methodology, as opposed to planting metal complexes onto electrode surfaces,<sup>10–16,18</sup> enables reaction mechanism elucidation via solution kinetic and spectroscopic monitoring of key steps occurring and intermediates forming during catalysis.<sup>15,19–23</sup>

Thus, [{(TMPA)Cu<sup>II</sup>}<sub>2</sub>( $\mu$ -1,2-O<sub>2</sub><sup>2-</sup>)]<sup>2+</sup> (**A1**) (TMPA (tris(2-pyridylmethyl)amine)) has structure **A** (Scheme 1) and when formed, it is reductively O–O cleavage (and protonated) to give water, that in preference to simple protonation leading to H<sub>2</sub>O<sub>2</sub>.<sup>17a,24</sup> Precursor complexes leading to **B** or **C** are also catalysts for 4e<sup>-</sup>/4H<sup>+</sup> reduction of O<sub>2</sub>.<sup>17b</sup> The course of reaction for [Cu<sup>II</sup><sub>2</sub>(N3)(H<sub>2</sub>O)<sub>2</sub>](ClO<sub>4</sub>)<sub>4</sub> [**B1**; N3 = -(CH<sub>2</sub>)<sub>3</sub>-linked bis[(2-(2-pyridyl)ethyl)amine]<sup>25</sup> versus [Cu<sup>II</sup>(BzPY1)(EtOH)](ClO<sub>4</sub>)<sub>2</sub> [**C1**; BzPY1 = N,N-bis[2-(2-pyridyl)ethyl]benzylamine],<sup>26</sup> differs.<sup>17b</sup> One important finding is that for **B1**, the observed intermediate species, [Cu<sup>II</sup><sub>2</sub>(N3)( $\mu$ - $\eta^2$ :  $\eta^2$ -O<sub>2</sub><sup>2-</sup>)]<sup>2+</sup>, does not convert to the isomeric structure type **C**; rather, it is directly reduced by the ferrocenyl reductant leading to O–O cleavage to give water.

Thus far, there has been no report on the selective two-electron reduction of O<sub>2</sub> to H<sub>2</sub>O<sub>2</sub> by one-electron reductants using copper complex catalysts. Herein, we describe such a case involving dicopper complex chemistry giving a fourth known Cu<sub>2</sub>O<sub>2</sub> structural type.<sup>27</sup> A reduced species [Cu<sup>I</sup><sub>2</sub>(LO)]<sup>+</sup> (**D3**) reacts with O<sub>2</sub> to give [Cu<sup>II</sup><sub>2</sub>(LO)(OO)]<sup>+</sup> (**D**),<sup>28</sup> which possesses an ‘end-on’ peroxy-coordination (Scheme 2). The peroxy ligand in **D** is basic and facile protonation leads to the  $\mu$ -1,1-hydroperoxy dicopper(II) complex [Cu<sup>II</sup><sub>2</sub>(LO)(OOH)]<sup>2+</sup> (**D4**) (Scheme 2).<sup>29</sup> As will be shown in this report, this step is one of the keys to providing the observation of overall catalytic two-electron two-proton reduction of dioxygen to hydrogen peroxide (eq 1):

Further, we have been able to dissect this catalytic process, confirming the reaction stoichiometry, elucidating its kinetic behavior and identifying various intermediates.

The insights obtained from this study and comparison to the 4e<sup>-</sup>/4H<sup>+</sup> O<sub>2</sub>-reduction catalysis proceeding via O<sub>2</sub>-complexes **A**, **B** and **C** can or will allow us to explain how and why use of various ligands and their complexes lead to 4e<sup>-</sup>/4H<sup>+</sup> O<sub>2</sub>-reduction while others (or at least

one other) provides for  $2e^-/2H^+$  O<sub>2</sub>-reduction to H<sub>2</sub>O<sub>2</sub>. The basics obtained here should serve as useful and broadly applicable principles for future design of catalysts for use in substrate oxidations and/or fuel cells, H<sub>2</sub>O<sub>2</sub> itself as a product having considerable potential utility. Hydrogen peroxide has attracted increasing attention as a promising candidate as a sustainable and clean energy carrier,<sup>30–33</sup> because the free enthalpy change of the decomposition of hydrogen peroxide producing water and dioxygen is as large as  $-210.71\text{ kJ mol}^{-1}$ .<sup>34</sup> Hydrogen peroxide has also been used as a highly efficient and environmentally benign oxidant in terms of delignification efficiency and reducing ecological impact.<sup>35–36</sup>

## Experimental Section

### Materials

Grade quality solvents and chemicals were obtained commercially and used without further purification unless otherwise noted. Decamethylferrocene (Fc<sup>\*</sup>) (97%), octamethylferrocene (Me<sub>8</sub>Fc), 1,1'-dimethylferrocene (Me<sub>2</sub>Fc), ferrocene (Fc), hydrogen peroxide (50%), and HOTF (99%) were purchased from Aldrich Co., USA, and NaI (99.5%) from Junsei Chemical Co., Japan. Acetone was purchased from JT Baker, USA and used whether without further purification for non-air-sensitive experiment or dried and distilled under argon then deoxygenated by bubbling with argon for 30–45 min and kept over activated molecular sieve (4 Å) for air-sensitive experiments.<sup>37</sup> Preparation and handling of air-sensitive compounds were performed under Ar atmosphere (<1 ppm O<sub>2</sub>, <1 ppm H<sub>2</sub>O) in a glove box (Korea Kiyon Co., Ltd.). The copper complexes [Cu<sup>I</sup><sub>2</sub>(LH)(CH<sub>3</sub>CN)<sub>2</sub>](SbF<sub>6</sub>)<sub>2</sub> (LH = *m*-xylene-linked bis[(2-(2-pyridyl)ethyl)amine]<sup>27</sup> as a precursor to [Cu<sup>II</sup><sub>2</sub>(LO)(OH)](SbF<sub>6</sub>)<sub>2</sub> (**D1**) and [Cu<sup>I</sup><sub>2</sub>(LO)]BArF (**D3**) (BArF<sup>-</sup> = B(C<sub>6</sub>F<sub>5</sub>)<sub>4</sub><sup>-</sup>) for the low temperature generation of hydroperoxo species were prepared according to the literature procedures.<sup>29</sup> The use of BArF<sup>-</sup> rather than SbF<sub>6</sub><sup>-</sup> as counter-anion was due to the resulting higher stability and ease of handling of the air-sensitive dicopper(I) complex as well as the greater stability of the peroxy and hydroperoxo species that were then generated. Anal. Calcd. for (C<sub>36</sub>H<sub>40</sub>N<sub>6</sub>O<sub>2</sub>F<sub>12</sub>Cu<sub>2</sub>Sb<sub>2</sub>)•CH<sub>3</sub>CN: C, 37.15; H, 3.53; N, 7.98. Found: C, 37.24; H, 3.69; N, 8.32.

### Instrumentation

UV-vis spectra were recorded on a Hewlett Packard 8453 diode array spectrophotometer equipped with a UNISOKU Scientific Instruments Cryostat USP-203A for low-temperature experiments or an UNISOKU RSP-601 stopped-flow spectrometer equipped with a MOS-type highly sensitive photodiode array. Cyclic voltammetry (CV) and differential pulse voltammetry (DPV) measurements were performed on an ALS 630B electrochemical analyzer and voltammograms were measured in deaerated acetone containing 0.20 M TBAPF<sub>6</sub> as a supporting electrolyte at  $-40\text{ }^\circ\text{C}$ . The temperature was controlled by use of an MeCN/liquid N<sub>2</sub> bath. A conventional three-electrode cell was used with a gold working electrode (surface area of 0.3 mm<sup>2</sup>) and a platinum wire as the counter electrode. The Pt working electrode (BAS) was routinely polished with BAS polishing alumina suspension and rinsed with acetone before use. The potentials were measured with respect to the Ag/AgNO<sub>3</sub> (0.010 M) reference electrode. All potentials (vs Ag/Ag<sup>+</sup>) were converted to values vs SCE by adding 0.29 V.<sup>38</sup> All electrochemical measurements were carried out under an atmospheric pressure of nitrogen. X-band EPR spectra were recorded at 5 K using X-band Bruker EMX-plus spectrometer equipped with a dual mode cavity (ER 4116DM). Low temperature was achieved and controlled with an Oxford Instruments ESR900 liquid He quartz cryostat with an Oxford Instruments ITC503 temperature and gas flow controller. The experimental parameters for EPR spectra were as follows: Microwave frequency = 9.6483 GHz, microwave power = 1.0 mW, modulation amplitude = 10 G, gain =  $5 \times 10^2$ ,

modulation frequency = 100 kHz, time constant = 81.92 ms, and conversion time = 81.00 ms.

### Kinetic Measurements

The spectral change in the UV-visible were recorded on a Hewlett Packard 8453 diode array spectrophotometer equipped with Unisoku thermostated cell holder for low-temperature experiments. In a typical catalytic reaction, the quartz cuvette is loaded with 3 mL of 10:30:1 Fc<sup>\*</sup>/HOTF/**D1** ( $1.0 \times 10^{-4}$  M) in a degassed solution of acetone. Then O<sub>2</sub> gas (99.999%) was introduced into the solution through a needle for 1 min to make it O<sub>2</sub><sup>-</sup> saturated. The catalytic reaction is monitored by the increase in the absorbance at 780 nm corresponding to the formation of the ferrocenium cation (Fc<sup>\*+</sup>) ( $\epsilon = 5.8 \times 10^2$  M<sup>-1</sup> cm<sup>-1</sup>). The  $\epsilon$  value of Fc<sup>\*+</sup> was confirmed by the electron-transfer oxidation of Fc<sup>\*</sup> with *p*-benzoquinone in the presence of HOTF (see Figure S1 in Supporting Information (SI)).

The limiting concentration of O<sub>2</sub> in an acetone solution was prepared by injecting a different aliquots of an O<sub>2</sub>-saturated acetone solution ( $1.1 \times 10^{-2}$  M),<sup>39</sup> prepared by bubbling O<sub>2</sub> through argon-saturated acetone in a Schlenk tube for 30 min at 298 K.<sup>40</sup> In case of the experiment involving 2.2 equiv of O<sub>2</sub> relative to **D1** ( $1.0 \times 10^{-4}$  M), 60  $\mu$ L of the O<sub>2</sub><sup>-</sup> saturated acetone solution were injected into the cuvette with the total volume of 3 mL.

### Iodometric Titration for the Determination of H<sub>2</sub>O<sub>2</sub>

The amount of H<sub>2</sub>O<sub>2</sub> was determined by titration with iodide ion.<sup>41</sup> The diluted acetone solution (1/15) of the reduced product of O<sub>2</sub> was treated with an excess of NaI. The amount of I<sub>3</sub><sup>-</sup> formed was then quantified using its visible spectrum ( $\lambda_{\text{max}} = 361$  nm,  $\epsilon = 2.5 \times 10^4$  M<sup>-1</sup> cm<sup>-1</sup>). The controlled reactions including the reaction of **D1** complex with NaI, H<sub>2</sub>O<sub>2</sub> with NaI in the absence of **D1** and H<sub>2</sub>O<sub>2</sub> with NaI in the presence of **D1** were also performed in order to elucidate the exact amount of H<sub>2</sub>O<sub>2</sub> generated in the catalytic two electron reduction of O<sub>2</sub> by Fc<sup>\*</sup>.

### Low Temperature Experiments Concerning the Generation of [Cu<sup>II</sup><sub>2</sub>(LO)(OOH)]<sup>2+</sup>

(**D4**) Under an argon atmosphere within a glove box, [Cu<sup>I</sup><sub>2</sub>(LO)]BARF (**D3**) ( $7.0 \times 10^{-5}$  M) was dissolved in 3 mL of O<sub>2</sub>-free acetone giving a bright yellow solution. The cuvette was fully sealed with septum and quickly removed from the glove box and cooled to -80 °C in a Hewlett Packard 8453 diode array spectrophotometer equipped with Unisoku thermostated cell holder. O<sub>2</sub> was gently bubbled through the reaction solution and 1 equiv HOTF dissolved in CH<sub>2</sub>Cl<sub>2</sub> was quickly added by syringe. The formation of the hydroperoxo species was followed by the change in the absorbance at 395 nm. The 3 value of [Cu<sup>II</sup><sub>2</sub>(LO)(OOH)]<sup>2+</sup> (**D4**) was determined to be  $1.0 \times 10^4$  M<sup>-1</sup> cm<sup>-1</sup> measured in acetone at -80 °C.

### Low Temperature Experiments Concerning the reaction of Mixed-valence [Cu<sup>II</sup>Cu<sup>I</sup>(LO)]<sup>2+</sup> (**D2**) with O<sub>2</sub>

Under an argon atmosphere within a glove box, **D1** ( $1.0 \times 10^{-4}$  M) was mixed with Fc<sup>\*</sup> ( $1.0 \times 10^{-4}$  M) and TFA ( $1.0 \times 10^{-3}$  M) in 3 mL O<sub>2</sub>-free acetone giving an orange solution. The cuvette was fully sealed with septum and quickly removed from the glove box and cooled down to -80 °C. O<sub>2</sub> gas was then gently bubbled through the solution using a needle. The formation of the hydroperoxo species was followed by the change in the absorbance at 395 nm.

### DFT Calculations

Density-functional theory (DFT) calculations were performed on a 32CPU workstation (PQS, Quantum Cube). Geometry optimizations were carried out using the Becke3LYP

functional and lanl2dz basis set as implemented in the Gaussian 09 program Revision A. 02.<sup>42</sup> Graphical outputs of the computational results were generated with the Gauss View software program (ver. 3.09) developed by Semichem, Inc.<sup>43</sup>

## Results and Discussion

### Mechanism of D1-Catalyzed Two-Electron Reduction of O<sub>2</sub> with Fc<sup>\*</sup> to H<sub>2</sub>O<sub>2</sub>

For the sake of clarifying and a better understanding of this study, we prefer to present the mechanism of [Cu<sup>II</sup><sub>2</sub>(LO)(OH)]<sup>2+</sup> (**D1**) catalyzed two-electron reduction of O<sub>2</sub> with Fc<sup>\*</sup> at the beginning, as shown in Scheme 3. What follows is our presentation of how the observations and data lead to this catalytic mechanism.

No oxidation of Fc<sup>\*</sup> by O<sub>2</sub> occurred in the absence and presence of [Cu<sup>II</sup><sub>2</sub>(LO)(OH)]<sup>2+</sup> (**D1**) in acetone (Figure S2 in SI). However, when trifluoroacetic acid (HOTF) was added to the Fc<sup>\*</sup>-O<sub>2</sub>-**D1** system at 223 K, efficient oxidation of Fc<sup>\*</sup> by O<sub>2</sub> occurred to yield Fc<sup>\*+</sup> as indicated by an increase in the absorbance at 780 nm due to Fc<sup>\*+</sup> (Figure 1). When more than two equiv of Fc<sup>\*</sup> relative to O<sub>2</sub> (i.e., limiting [O<sub>2</sub>]) were employed,<sup>39</sup> still only two equiv Fc<sup>\*+</sup> ( $\lambda_{\text{max}} = 780 \text{ nm}$ ) were formed, even in the presence of excess HOTF (Figure S3 in SI). The stoichiometry of the catalytic oxidation of Fc<sup>\*</sup> by O<sub>2</sub> is given by eq 1 (Introduction). The formation of H<sub>2</sub>O<sub>2</sub> was confirmed by the iodometric titration (Figure S4 in SI). The amount of I<sub>3</sub><sup>-</sup> produced ( $\lambda_{\text{max}} = 360 \text{ nm}$ ) was the same as that produced by the reaction of the stoichiometric amount of H<sub>2</sub>O<sub>2</sub> with I<sup>-</sup> (Figure S5 in SI). Thus, selective two-electron reduction of O<sub>2</sub> with Fc<sup>\*</sup> occurred in the presence of excess HOTF and a catalytic amount of **D1** in acetone at 223 K. When the temperature was raised to 298 K, the yield of H<sub>2</sub>O<sub>2</sub> decreased to 55% because of competition with the direct reduction of H<sub>2</sub>O<sub>2</sub> by Fc<sup>\*</sup> (Figure S6 in SI). Thus, the kinetic analyses were performed at 223 K (vide infra).

The rate of formation of Fc<sup>\*+</sup> (inset of Figure 1) obeyed first-order kinetics (Figure S7 in SI). The observed first-order rate constant increased linearly with increasing concentration of the catalyst (**D1**) as shown in Figure 2a. The dependence of  $k_{\text{obs}}$  on concentration of HOTF was also examined and the results are shown in Figure 2b, where the  $k_{\text{obs}}$  value remains the same with increasing concentration of HOTF. The dependence of  $k_{\text{obs}}$  on concentration of O<sub>2</sub> is shown in Figure 2c, where the  $k_{\text{obs}}$  value increases linearly with increasing concentration of O<sub>2</sub> and a clear intercept is recognized (Figure S8 in SI). Thus, the rate of formation of Fc<sup>\*+</sup> is given by eq 2,

$$\frac{d[\text{Fc}^{*+}]}{dt} = k_{\text{cat}}[\mathbf{D1}][\text{Fc}^*] \quad (2)$$

$$k_{\text{cat}} = k_1 + k_2[\text{O}_2] \quad (3)$$

where  $k_{\text{cat}}$  is the second-order catalytic rate constant,  $k_1$  corresponds to the second-order rate constant, which is independent of concentration of O<sub>2</sub>, and  $k_2$  corresponds to the rate constant which is dependent of concentration of O<sub>2</sub>. In the next section, each step in the catalytic cycle in Scheme 3 is examined in detail to reconcile the kinetic formulation given by eqs 2 and 3.

### Protonation of [Cu<sup>II</sup><sub>2</sub>(LO)(OH)](SbF<sub>6</sub>)<sub>2</sub> (**D1**)

Because no oxidation of Fc<sup>\*</sup> by O<sub>2</sub> occurred in the presence of **D1** without added acid, a spectral titration of **D1** with HOTF was carried out (Figure 3a). The result is that the absorption band at 378 nm due to [Cu<sup>II</sup><sub>2</sub>(LO)(OH)]<sup>2+</sup> is red-shifted to 420 nm; a clean isosbestic point is observed at 430 nm. This spectral change is well analyzed by assuming

formation of the protonated complex  $[\text{Cu}^{\text{II}}_2(\text{LO})(\text{OTF})]^{2+}$  (**D1-OTF**); confirming evidence comes from a separate examination of the 1:1 reaction of HOTF with authentic **D1**.<sup>44</sup> The protonation constant ( $K$ ) of **D1** to produce **D1-OTF** is determined by eq 4, where  $[\text{D1}]_0 = [\text{D1}] + [\text{D1} - \text{HOTF}]$ ,  $[\text{D1}]_0$  and  $[\text{HOTF}]_0$  are

$$K = [\text{D1} - \text{HOTF}] / [\text{D1}][\text{HOTF}] = ([\text{D1}]_0 - [\text{D1}]) / \{([\text{HOTF}]_0 - [\text{D1}]_0 + [\text{D1}])[\text{D1}]\} \quad (4)$$

the initial concentrations of **D1** and HOTF. Eq 4 is easily converted to eq 5, where  $\alpha =$

$$\alpha^{-1} - 1 = K \{ [\text{HOTF}]_0 - (1 - \alpha)[\text{D1}]_0 \} \quad (5)$$

$[\text{D1}] / [\text{D1}]_0 = \Delta A / \Delta A_0$  ( $\Delta A$  is the absorbance change at 378 nm due to **D1** and  $\Delta A_0$  corresponds to the absorbance change when all **D1** molecules are converted to **D1-OTF**). A linear correlation between  $\alpha^{-1} - 1$  vs  $[\text{HOTF}]_0 - (1 - \alpha)[\text{D1}]_0$  shown in Figure 3b confirmed the validity of the assumption of the formation of  $[\text{Cu}^{\text{II}}_2(\text{LO})(\text{OTF})]^{2+}$  (**D1-OTF**). Then, the  $K$  value is determined from the slope of a linear plot of  $\alpha^{-1} - 1$  vs  $[\text{HOTF}]_0 - (1 - \alpha)[\text{D1}]_0$  (Figure 3b) to be  $1.6 \times 10^2 \text{ M}^{-1}$ . The temperature dependence of  $K$  was examined (Figure S9 in SI) and the van't Hoff plot (Figure S10 in SI) afforded  $\Delta H = -3.6 \text{ kcal mol}^{-1}$  and  $\Delta S = 2.1 \text{ cal K}^{-1} \text{ mol}^{-1}$ .

The binuclear Cu(II) complex  $[\text{Cu}^{\text{II}}_2(\text{LO})(\text{OH})]$  (**D1**) is EPR silent because of antiferromagnetic coupling of the two Cu(II) ions. The protonated complex **D1-OTF** was also EPR silent (Figure S11 in SI). This indicates that two Cu(II) ions still maintain an electronic/magnetic interaction after the protonation of **D1**. Because the catalytic reduction of  $\text{O}_2$  by  $\text{Fc}^*$  with **D1** was made possible only by the presence of TFA, the effect of protonation of **D1** by TFA on the one-electron reduction of **D1** was examined by cyclic voltammetry (CV) and difference pulse voltammetry (DPV) measurements. Figure 4a shows a CV of **D1** in acetone at 233 K. The irreversible cathodic peak current was observed at  $-0.71 \text{ V}$  vs SCE at a sweep rate of  $0.10 \text{ V s}^{-1}$  while the DPV exhibits the cathodic peak at  $-0.68 \text{ V}$  vs SCE. The cathodic peak is much more negative as compared to the one-electron oxidation potential of  $\text{Fc}^*$  ( $E_{\text{ox}} = -0.08 \text{ V}$  vs SCE).<sup>45–47,53,54</sup> This is the reason why no electron transfer from  $\text{Fc}^*$  to **D1** ensues, thus precluding copper(I) formation,  $\text{O}_2$ -reaction and  $\text{Fc}^*$  oxidation.

In the presence of HOTF, however, the DPV peak is shifted to a positive direction as shown in Figure 4b, where a first and also a second one-electron reduction peak for  $[\text{Cu}^{\text{II}}_2(\text{LO})(\text{OTF})]^{2+}$  (**D1-OTF**) are observed at  $0.18$  and  $0.00 \text{ V}$  vs SCE, respectively. This implied that a mixed-valence complex  $[\text{Cu}^{\text{II}}\text{Cu}^{\text{I}}(\text{LO})]^{2+}$  (**D2**) may (and does) form (vide infra). In the presence of  $\text{O}_2$ , a catalytic current for the reduction of  $\text{O}_2$  is observed at  $-0.02 \text{ V}$ , which corresponds to the second one-electron reduction of **D1-OTF** (Scheme 3) and the catalytic current increases with increasing concentration of  $\text{O}_2$  (Figure 4b).

### Two-Step Electron Transfer from $\text{Fc}^*$ to $[\text{Cu}^{\text{II}}_2(\text{LO})(\text{OTF})]^{2+}$ (**D1-OTF**)

As said, the  $E_{\text{ox}}$  value of  $\text{Fc}^*$  is more negative than the first and second one-electron potentials of **D1-OTF**, making electron transfer from  $\text{Fc}^*$  to **D1-OTF** thermodynamically feasible. Thus, we examined the dynamics of electron transfer from  $\text{Fc}^*$  to **D1-OTF**. In fact, electron transfer from  $\text{Fc}^*$  to **D1** in the presence of HOTF occurs by a two step process, this as not being unexpected based on the observation that two one-electron reduction peaks are observed, Figure 4b. Figure 5 shows the UV-vis changes corresponding to the first step in the presence of  $2.0 \text{ mM}$  HOTF at  $203 \text{ K}$ . At this temperature most **D1** molecules are converted to **D1-OTF** with  $2.0 \text{ mM}$  HOTF. The amount of  $\text{Fc}^{*+}$  produced in the first

electron transfer from  $\text{Fc}^*$  to **D1-OTF** is the same as the concentration of **D1** (0.10 mM). The rate of formation of  $\text{Fc}^{*+}$  obeyed pseudo-first-order kinetics at the initial stage of the reaction in the presence of HOTF (3.0 mM) in acetone at 203 K (Figure S12 in SI). The observed pseudo-first-order rate constant ( $k_{\text{obs}}$ ) increases linearly with increasing the concentration of  $\text{Fc}^*$  (Figure 6). The second-order rate constant ( $k_{\text{et1}}$ ) of electron transfer from  $\text{Fc}^*$  to **D1-OTF** was determined to be  $7.8 \text{ M}^{-1} \text{ s}^{-1}$  from the slope of a linear plot of  $k_{\text{obs}}$  vs  $[\text{Fc}^*]$  at 203 K.

Figure 7 shows UV-vis monitoring of the second step of electron transfer from  $\text{Fc}^*$  to **D1-OTF**, which corresponds to electron transfer from  $\text{Fc}^*$  to the mixed-valence complex,  $[\text{Cu}^{\text{II}}\text{Cu}^{\text{I}}(\text{LO})]^{2+}$  (**D2**). This could be separately generated by the one-electron reduction of **D1** with one equivalent of  $\text{Fc}^*$  in the presence of excess HOTF. EPR spectroscopic measurements confirmed the generation of **D2**, as this new species only exhibits signals due to the one Cu(II) moiety at  $g_{\parallel} = 2.27$  and  $g_{\perp} = 2.06$  (Figure 8), indicating that there is no delocalization of an electron between the Cu(I) and Cu(II) ions. A conproportionation reaction of a derived mixed-valence complex can be ruled out, since neither product of such a reaction, a dicopper(I) and phenolate (LO)-bridged dicopper(II) complex would be a simple copper(II) paramagnet. We note that with an unsymmetrical binucleating ligand very similar to LO, L'O, we previously also demonstrated the existence of a mixed-valence dicopper species  $[\text{Cu}^{\text{II}}\text{Cu}^{\text{I}}(\text{L}'\text{O})]^{2+}$  possessing very similar EPR spectroscopic characteristics as observed here.<sup>48</sup>

The kinetics of formation of  $\text{Fc}^{*+}$  in the second step electron transfer from  $\text{Fc}^*$  to  $\text{Cu}^{\text{II}}_2(\text{LO})(\text{OTf})^{2+}$  (**D1-OTF**) in the presence of HOTF (3.0 mM) in acetone at 213 K (Figure 7) also obeyed pseudo-first-order kinetics (Figure S13 in SI) and the observed pseudo-first-order rate constant ( $k_{\text{obs}}$ ) also increases linearly with increasing concentration of  $\text{Fc}^*$  (Figure 9). The second-order rate constant for electron transfer from  $\text{Fc}^*$  to **D1-OTF** was determined from the slope of a linear plot of  $k_{\text{obs}}$  vs  $[\text{Fc}^*]$  to be  $1.4 \text{ M}^{-1} \text{ s}^{-1}$  at 213 K. At this temperature the first step electron transfer was too fast to determine the  $k_{\text{et1}}$  value. When the temperature is raised to 223 K, the  $k_{\text{et2}}$  value increased to  $5.4 \text{ M}^{-1} \text{ s}^{-1}$ . It is important to note that the  $k_{\text{et2}}$  value determined from the second step electron transfer from  $\text{Fc}^*$  to **D1** in the presence of HOTF (2.0 mM) is one-half of the  $k_1$  value ( $11 \text{ M}^{-1} \text{ s}^{-1}$ ) obtained as an intercept in Figure 2b. This clearly indicates that the second step electron transfer from  $\text{Fc}^*$  to **D1** in the presence of HOTF is the rate-determining step in the catalytic cycle in Scheme 3, because once one equiv of  $\text{Fc}^{*+}$  is formed by electron transfer from  $\text{Fc}^*$  to **D2**, another equiv of  $\text{Fc}^{*+}$  is rapidly formed by the first step electron transfer from  $\text{Fc}^*$  to **D1-OTF**. In such a case, the rate of formation of  $\text{Fc}^{*+}$  is derived from Scheme 3 as given by eq 6. By comparing eq 6 with the

$$\frac{d[\text{Fc}^{*+}]}{dt} = 2k_{\text{et2}}[\text{D1}][\text{Fc}^*] \quad (6)$$

experimental results (eqs 1 and 2),  $k_1$  in  $k_{\text{cat}}$  (eq 2) corresponds to  $2k_{\text{et2}}$ , i.e.,  $k_{\text{et2}} = (1/2)k_1(\text{intercept})$ .

The temperature dependence of  $k_{\text{et2}}$  was examined and the Eyring plot (Figure S14 in SI) afforded the activation enthalpy ( $\Delta H = 11.2 \pm 0.2 \text{ kcal mol}^{-1}$ ) and activation entropy ( $\Delta S = 2 \pm 2 \text{ cal K}^{-1} \text{ mol}^{-1}$ ). An activation entropy close to zero was previously reported for electron transfer from ferrocene derivatives to Cu(II) complexes.<sup>47</sup>

## Cu(II)-Peroxo and -Hydroperoxo Intermediates in the Stoichiometric Two-Electron Reduction of O<sub>2</sub> by Fc\* in the Presence of HOTF

The Cu(II)-oxygen intermediates likely involved in the catalytic two-electron reduction of O<sub>2</sub> by Fc\* in Scheme 3 were examined by following the reaction of an isolated sample of dicopper(I) complex, [Cu<sup>I</sup><sub>2</sub>(LO)]<sup>+</sup> (**D3**), with O<sub>2</sub> at 193 K. When O<sub>2</sub> was introduced to an acetone solution of **D3**, the peroxy complex [Cu<sup>II</sup><sub>2</sub>(LO)(OO)]<sup>+</sup> (**D**) which should form very rapidly (see Introduction) is however slowly converted to the hydroperoxo complex, [Cu<sup>II</sup><sub>2</sub>(LO)(OOH)]<sup>2+</sup> (**D4**) as indicated by an increase in the absorption band at 395 nm. This can be explained by the occurrence of the reaction of [Cu<sup>II</sup><sub>2</sub>(LO)(OO)]<sup>+</sup> (**D**) with residual water in acetone (Figure 10a). Instead, when one equiv of HOTF is added to the solution containing **D** the hydroperoxo complex **D4** forms very rapidly (Figure 10b), as expected.<sup>29</sup>

When one equiv of HOTF was added before the reaction of [Cu<sup>I</sup><sub>2</sub>(LO)]<sup>+</sup> (**D3**) with O<sub>2</sub>, an immediate transformation occurs to give only hydroperoxo complex [Cu<sup>II</sup><sub>2</sub>(LO)(OOH)]<sup>2+</sup> (**D4**) (Figure 11a). This indicates that the protonation of the peroxy complex with HOTF is much faster than the formation of the peroxy complex itself. In contrast with the case of  $\mu$ - $\eta^2$ :  $\eta^2$ -peroxy dicopper(II) and bis- $\mu$ -oxo dicopper(III) complexes, which were readily reduced by Fc\*,<sup>29</sup> no electron transfer from Fc\* to the hydroperoxo complex [Cu<sup>II</sup><sub>2</sub>(LO)(OOH)]<sup>2+</sup> (**D4**) occurred as shown in Figure 11b, where the absorption spectrum due to **D4** was not changed by the addition of Fc\*. This is the reason why the selective two-electron reduction of O<sub>2</sub> by Fc\* occurs, i.e., the hydroperoxo-dicopper(II) complex **D4** is not susceptible to reduction, thus with catalyst and HOTF, H<sub>2</sub>O<sub>2</sub> is produced.

When HOTF was further added to an acetone solution of [Cu<sup>II</sup><sub>2</sub>(LO)(OOH)]<sup>2+</sup> (**D4**), the absorption band due to **D4** disappeared as the concentration of HOTF increased (Figure 12a) indicating that this reaction directly produces [Cu<sup>II</sup><sub>2</sub>(LO)(OTF)]<sup>2+</sup> (**D1-OTF**) and hydrogen peroxide. The amount of 10 equiv of HOTF is enough for a quantitative reaction to take place (Figure 12b).

## The Reactivity of Mixed-Valence [Cu<sup>II</sup>Cu<sup>I</sup>(LO)]<sup>2+</sup> (**D2**) with O<sub>2</sub> in the Presence of HOTF

The electron-transfer reduction of [Cu<sup>II</sup><sub>2</sub>(LO)(OTF)]<sup>2+</sup> (**D1-OTF**) with Fc\* with under single turnover conditions without O<sub>2</sub> clearly shows that the two-electron reduction takes place in two successive steps in which the second step is slower and this is the rate-determining step in the catalytic cycle in Scheme 3 as described above (see also Figures 5 and 7). Under the catalytic conditions, however, the observed catalytic rate constant (*k*<sub>cat</sub>) in the presence of O<sub>2</sub> is larger than twice the rate constant of the second step electron transfer, *k*<sub>cat</sub> > 2*k*<sub>et2</sub>. This suggests that the initial electron-transfer reduction of **D1-OTF** may be followed by the reaction with O<sub>2</sub> in addition to a second-step electron transfer. This possibility was tested by directly examining the reactivity of the mixed-valence [Cu<sup>II</sup>Cu<sup>I</sup>(LO)]<sup>2+</sup> (**D2**) species with O<sub>2</sub> and in the presence of HOTF.

When O<sub>2</sub> is introduced to an acetone solution of [Cu<sup>II</sup>Cu<sup>I</sup>(LO)]<sup>2+</sup> (**D2**) at 193 K, the hydroperoxo complex [Cu<sup>II</sup><sub>2</sub>(LO)(OOH)]<sup>2+</sup> (**D4**) is immediately formed (Figure 13) and is then protonated in the presence of excess acid to give off hydrogen peroxide (see the inset of Figure 13). The amount of **D4** produced is about the one-half of the amount of **D2** judging from a comparison of the results in Figure 13 with those in Figure 11. This indicates that the reaction of **D2** with O<sub>2</sub> affords an O<sub>2</sub>-adduct of **D2**, a putative superoxo-dicopper(II) species [Cu<sup>II</sup><sub>2</sub>(LO)(O<sub>2</sub><sup>•-</sup>)]<sup>2+</sup> ([Cu<sup>II</sup><sub>2</sub>(O<sub>2</sub><sup>•-</sup>)]<sup>2+</sup>), which is reduced by a second molecule of [Cu<sup>II</sup>Cu<sup>I</sup>(LO)]<sup>2+</sup> (**D2**) and then protonated to give ~ 0.5 equiv of **D4**. Under catalytic conditions, however, [Cu<sup>II</sup><sub>2</sub>(LO)(O<sub>2</sub><sup>•-</sup>)]<sup>2+</sup> may be reduced by Fc\* that is present to produce one equiv of **D4**. Thus, the full catalytic cycle may not actually proceed via dicopper(I)

complex  $[\text{Cu}^{\text{I}}_2(\text{LO})]^+$  (**D3**) or peroxodicopper(II) complex  $[\text{Cu}^{\text{II}}_2(\text{LO})(\text{OO})]^+$  (**D**), but is “short-circuited” as shown in Scheme 4 (and this is also included in Scheme 3).

### Protonation vs Electron-Transfer Reduction of $[\text{Cu}^{\text{II}}_2(\text{LO})(\text{OOH})]^{2+}$ (**D4**)

Concerning the fact that **D4** undergoes protonation releasing hydrogen peroxide, rather than reductive cleavage by  $\text{Fc}^*$ , as do complexes with an dioxygen derived “trans”- $\mu$ -1,2-peroxo dicopper(II) (**A**),  $\mu$ -  $\eta^2$ :  $\eta^2$ -peroxo dicopper(II) (**B**) or bis- $\mu$ -oxo dicopper(III) (**C**) structure (see Introduction) complexes, one can consider a number of points. For one thing, see the DFT-optimized structure of **D4** shown in Figure 14 together with the LUMO orbital (for the calculation, see the Experimental Section). The optimized structure does possess a  $\mu$ -1,1-OOH ligand as previously proposed based on physical-spectroscopic methods, and the two calculated Cu-O<sub>hydroperoxo</sub> distances in  $[\text{Cu}^{\text{II}}_2(\text{LO})(\text{OOH})]^{2+}$  (**D4**) are nearly the same (2.044 and 2.046 Å). Because the LUMO orbital is delocalized to not only the metal but also to the ligands, the one-electron reduction of **D4** may not (and does not) lead to O-O bond cleavage for the further reduction to water. Instead,  $[\text{Cu}^{\text{II}}_2(\text{LO})(\text{OOH})]^{2+}$  (**D4**) releases  $\text{H}_2\text{O}_2$  upon protonation.

Another point is that it has been shown that in copper complexes the O–O bond becomes stronger upon protonation (–OOH) or alkylation (–OOR).<sup>49</sup> Thus, a relatively stronger O–O bond would in the presence of protons undergo copper-O cleavage giving  $\text{H}_2\text{O}_2$  rather than O–O cleavage eventually leading to water (and the  $4e^-/4\text{H}^+$  reduction of  $\text{O}_2$ ). The bonding within a  $\mu$ -  $\eta^2$ :  $\eta^2$ -peroxo dicopper(II)  $\text{Cu}_2\text{O}_2$  core is well known to produce very weak O–O bonds, possessing  $\nu(\text{O–O}) = 710$ – $760 \text{ cm}^{-1}$  (see Scheme 2). Thus, such complexes would be more susceptible to O–O reductive cleavage by  $\text{Fc}^*$  and protons, just as we have recently reported for the case of  $[\text{Cu}^{\text{II}}_2(\text{N}3)(\mu\text{-}\eta^2\text{:}\eta^2\text{-O}_2^{2-})]^{2+}$  (see Introduction).<sup>17b,50</sup> This is further supported by calculations on the LUMO of  $[\text{Cu}^{\text{II}}_2(\text{N}3)(\mu\text{-}\eta^2\text{:}\eta^2\text{-O}_2^{2-})]^{2+}$  (Figure 15a) which show it to be mainly localized at the anti-bonding O–O bond orbitals. And also  $[(\text{BzPY1})\text{Cu}^{\text{III}}]_2(\mu\text{-O}_2^{2-})_2]^{2+}$ , formed from reduction of  $[\text{Cu}^{\text{II}}(\text{BzPY1})(\text{EtOH})](\text{ClO}_4)_2$  (**C1**) and which promote bis- $\mu$ -oxo-dicopper(III) formation, as in this case, would likely promote  $4e^-/4\text{H}^+$  reduction of  $\text{O}_2$ . Note that for  $[(\text{BzPY1})\text{Cu}^{\text{III}}]_2(\mu\text{-O}_2^{2-})_2]^{2+}$ , the LUMO is mainly localized at the cleaved oxygen atom orbitals (Figure 15b).

What is perhaps a puzzle at this point, is that the (TMPA)-copper system, which provides for chemistry leading to  $[(\text{TMPA})\text{Cu}^{\text{II}}]_2(\mu\text{-1,2-O}_2^{2-})]^{2+}$  (**A1**) also gives rise to O–O reductive cleavage chemistry (vide supra).<sup>17a</sup> Yet, the O–O bond in this complex is strong,  $\nu(\text{O–O}) \sim 830 \text{ cm}^{-1}$ .<sup>51</sup> One may conjecture that the peroxy group in **A1** is well protected relative to the –OOH group in  $[\text{Cu}^{\text{II}}_2(\text{LO})(\text{OOH})]^{2+}$  (**D4**), and that protonation of the latter is extremely fast, while for **A1**, outer-sphere proton-coupled electron-transfer reduction by  $\text{Fc}^*$  easily proceeds. Certainly other factors may come into play, and a more rigorous experimental and theoretical understanding concerning preference for protonation or reduction surely will come about as more examples of both  $4e^-/4\text{H}^+$   $\text{O}_2$ -reduction to water and  $2e^-/2\text{H}^+$  reduction of  $\text{O}_2$  to hydrogen peroxide are found and investigated in detail.

### Summary and Conclusion

A binuclear copper(II) complex ( $[\text{Cu}^{\text{II}}_2(\text{LO})(\text{OH})]^{2+}$ ) acts as an efficient catalyst for the selective two-electron reduction of  $\text{O}_2$  by  $\text{Fc}^*$  with HOTF in acetone as shown in Scheme 3. The protonation of  $[\text{Cu}^{\text{II}}_2(\text{LO})(\text{OH})]^{2+}$  with HOTF results in formation of  $[\text{Cu}^{\text{II}}_2(\text{LO})(\text{OTF})]^{2+}$ , which can be reduced by  $\text{Fc}^*$  via two step electron-transfer reactions to produce  $[\text{Cu}^{\text{I}}_2(\text{LO})]^+$  via the mixed valance complex ( $[\text{Cu}^{\text{II}}\text{Cu}^{\text{I}}(\text{LO})]^{2+}$ ). Binuclear Cu(I) complex  $[\text{Cu}^{\text{I}}_2(\text{LO})]^+$  reacts with  $\text{O}_2$  rapidly in the presence of HOTF to produce the hydroperoxo complex ( $[\text{Cu}^{\text{II}}_2(\text{LO})(\text{OOH})]^+$ ) via protonation of an intermediate peroxy complex ( $[\text{Cu}^{\text{II}}_2(\text{LO})(\text{OO})]$ ). Further protonation of  $[\text{Cu}^{\text{II}}_2(\text{LO})(\text{OOH})]^+$  with HOTF produces  $\text{H}_2\text{O}_2$ ,

accompanied by regeneration of  $[\text{Cu}^{\text{II}}_2(\text{LO})(\text{OTF})]^{2+}$ . The rate-determining step in the predominant catalytic cycle given in Scheme 3 is the second step electron transfer, thus  $\text{Fc}^*$  reduction of a mixed-valent complex  $[\text{Cu}^{\text{II}}\text{Cu}^{\text{I}}(\text{LO})]^{2+}$  where this is coupled with  $\text{O}_2$ -binding to produce peroxy complex  $[\text{Cu}^{\text{II}}_2(\text{LO})(\text{OO})]^+$ . However, another reaction pathway consists of direct  $\text{O}_2$ -reaction with  $[\text{Cu}^{\text{II}}\text{Cu}^{\text{I}}(\text{LO})]^{2+}$ , followed by electron-transfer reduction of an  $\text{O}_2$ -adduct that must be formed, to give peroxy complex  $[\text{Cu}^{\text{II}}_2(\text{LO})(\text{OO})]^+$  (Scheme 4).

This is the first selective two-electron reduction of  $\text{O}_2$  by a one-electron reductant with a copper complex acting as a catalyst. Future modifications of the supporting ligand may improve the catalytic activity for the selective two-electron reduction of  $\text{O}_2$  to  $\text{H}_2\text{O}_2$ , the latter being a promising candidate as a renewable and clean energy source.<sup>30–32</sup>

44. Although the protonation equilibirum was well analyzed by assuming formation of a 1:1 complex between D1 and HOTF, whether H<sub>2</sub>O is still coordinated or not has yet to be clarified. However, ESI-MS analysis of such solutions which have  $\lambda_{\text{max}} = 420 \text{ nm}$  do show a prominent peak corresponding to the monocation  $\{[\text{Cu}^{\text{II}}_2(\text{LO})(\text{OTF})](\text{OTF})\}^+$

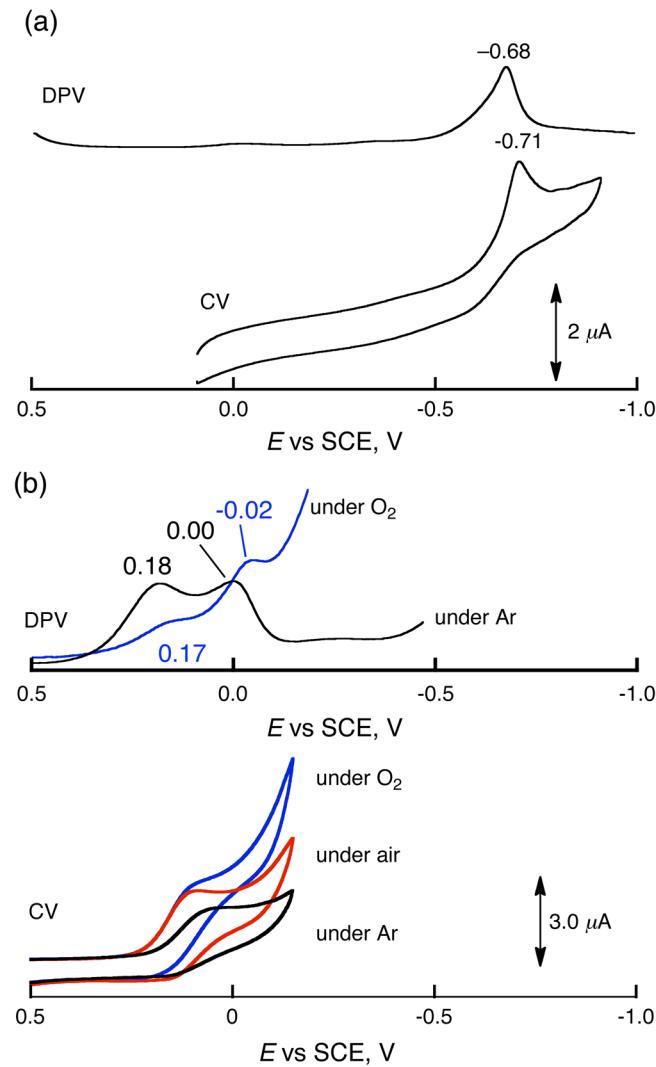

**Figure 1.**  
UV-vis spectral changes observed in the two-electron reduction of  $O_2$  catalyzed by  $[Cu^{II}_2(LO)(OH)]$  (**D1**) (0.040 mM) with  $Fc^*$  (1.0 mM) in the presence of HOTF (3.0 mM) in  $O_2$ -saturated acetone ( $[O_2] = 11.0$  mM) at 223 K. The Inset shows the time profile of the absorbance at 780 nm due to  $Fc^{*+}$ .

**Figure 2.**

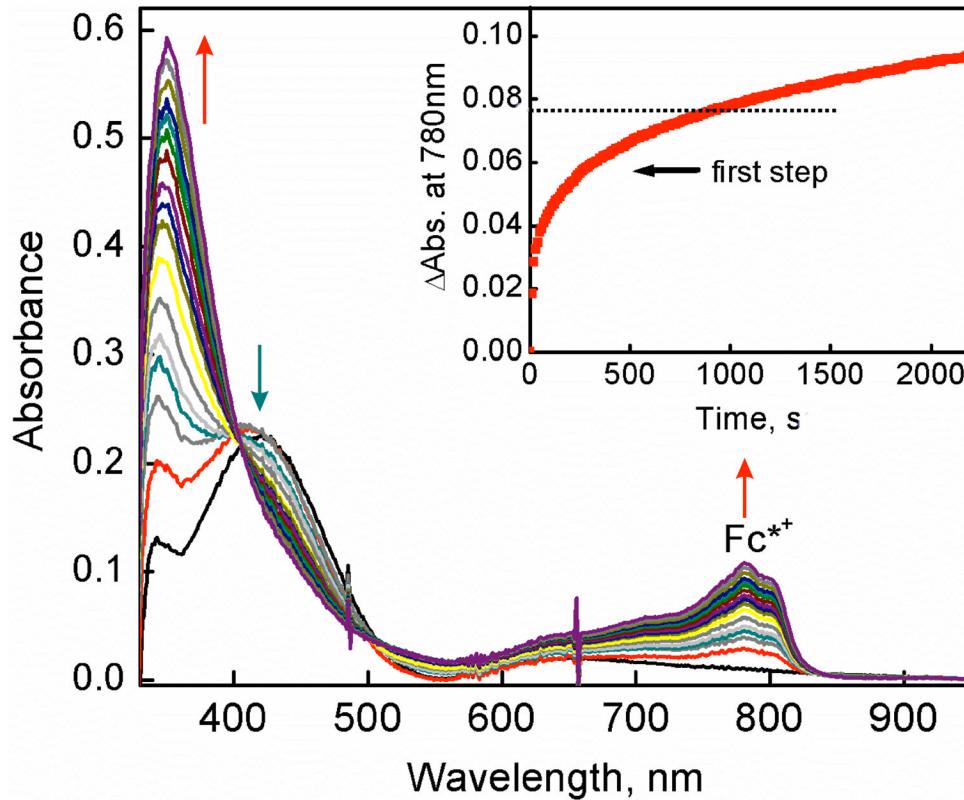

(a) Plot of the pseudo-first-order rate constants ( $k_{\text{obs}}$ ) vs concentrations of **D1** (black line) to determine second-order rate constant ( $k_{\text{cat}}$ ) for the two-electron reduction of  $\text{O}_2$  catalyzed by **D1** with  $\text{Fc}^*$  (1.0 mM) in the presence of TFA (3.0 mM) in  $\text{O}_2$ -saturated acetone ( $[\text{O}_2] = 11.0 \text{ mM}$ ) at 223 K. Red line shows plot of  $k_{\text{obs}}$  vs concentrations of TFA in the two-electron reduction of  $\text{O}_2$  catalyzed by **D1** (0.10 mM) with  $\text{Fc}^*$  (1.0 mM) in the presence of TFA in  $\text{O}_2$ -saturated acetone ( $[\text{O}_2] = 11.0 \text{ mM}$ ) at 223 K. (b) Plot of  $k_{\text{cat}}$  vs concentrations of  $\text{O}_2$  in the two-electron reduction of  $\text{O}_2$  catalyzed by **D1** (0.10 mM) with  $\text{Fc}^*$  (1.0 mM) in the presence of TFA (3.0 mM) in acetone at 223 K.

**Figure 3.**

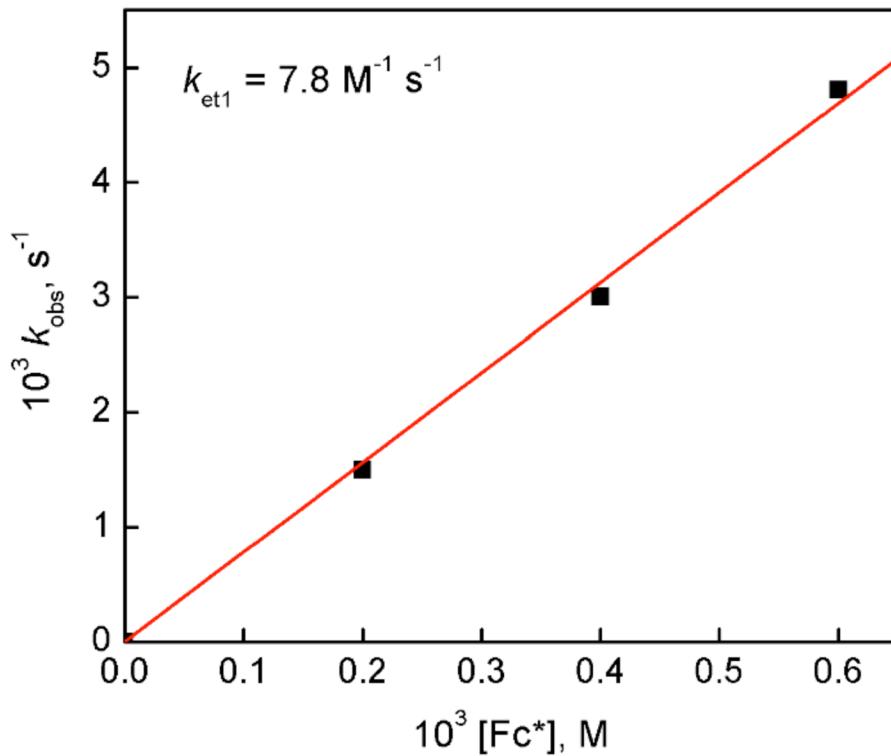

(a) UV-visible spectral changes of  $[\text{Cu}^{\text{II}}_2(\text{LO})(\text{OH})]^{2+}$  (**D1**) (0.20 mM) in the presence of HOTF (0.0 – 28.0 mM) in acetone at 298 K. (b) Plot of  $\alpha^{-1} - 1$  vs  $\{[\text{HOTF}]_0 - (1 - \alpha)[\text{D1}]_0\}$  to determine the equilibrium constants ( $K_{\text{eq}}$ ) in the protonation of **D1** upon addition of TFA (0.0 – 28.0 mM) into the solution of **D1** (0.20 mM) in acetone at 298 K.

**Figure 4.**

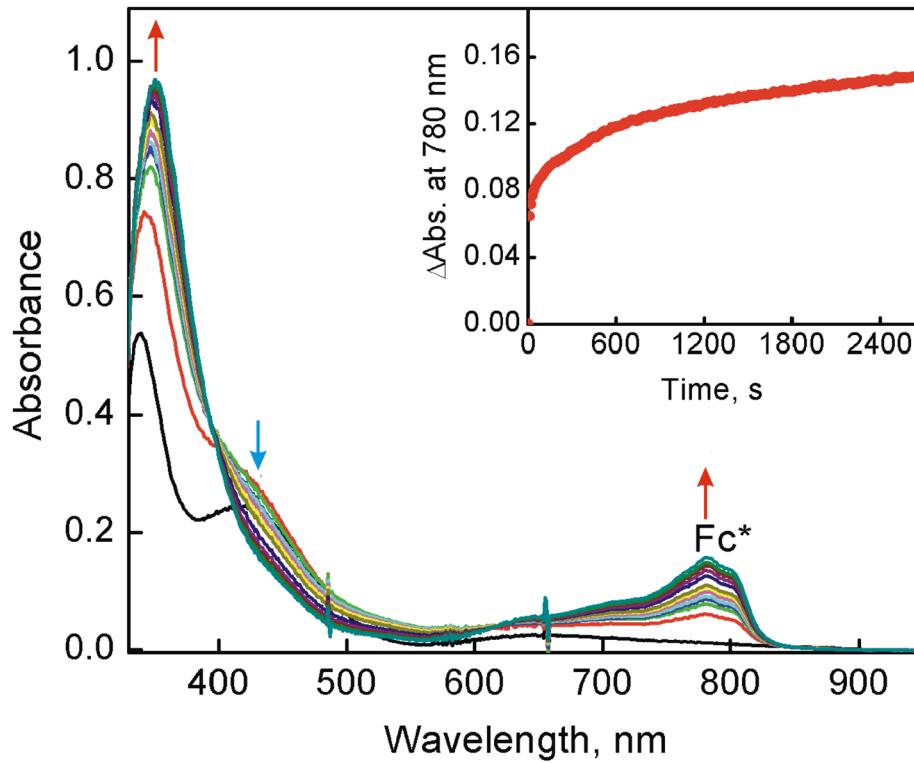

(a) Cyclic voltammograms and differential pulse voltammograms (DPV) of **D1** (2.0 mM) in the absence of HOTF in deaerated acetone at 233 K. (b) CV and DPV of **D1** (2.0 mM) in the presence of HOTF (50 mM) in deaerated (black), air-saturated (red) and  $\text{O}_2$ -saturated (blue) acetone at 233 K. TBAPF<sub>6</sub> (0.20 M) was used as an electrolyte.

**Figure 5.**

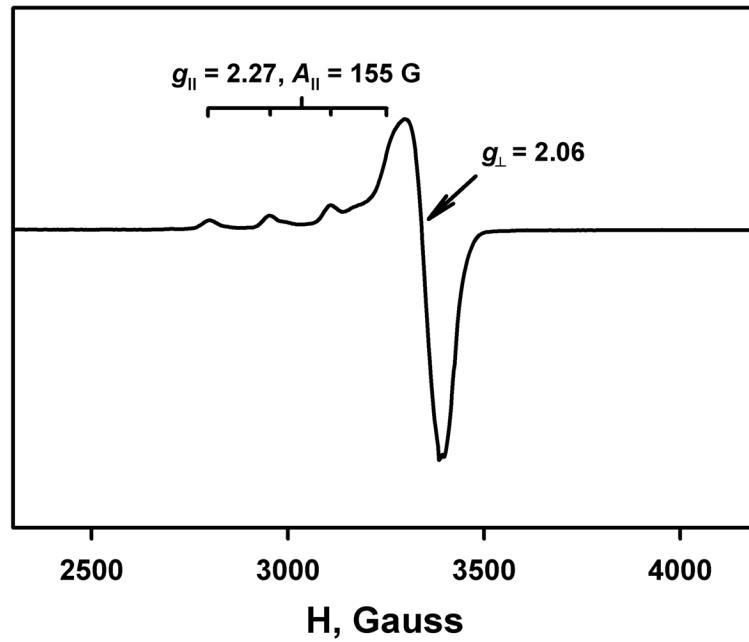

UV-vis spectral changes observed in the electron transfer from  $\text{Fc}^*$  (0.40 mM) to  $[\text{Cu}^{\text{II}}_2(\text{LO})(\text{OH})]$  (**D1**) (0.10 mM) in the presence of HOTF (2.0 mM) at 203 K. The Inset shows the time profile of the absorbance at 780 nm due to  $\text{Fc}^{*+}$ , showing that 1 equiv  $\text{Fc}^{*+}$  is formed in the first step, i.e., first phase. Note: the nonzero absorbance at 780 nm before the mixing of **D1** and  $\text{Fc}^*$  is due to *d-d* transition of **D1** complex, causing a large increase when the initial spectrum was recorded. This absorbance was subtracted from the total absorbance to give the absorbance due to  $\text{Fc}^{*+}$  to determine the rate constant.

**Figure 6.**

Plot of the pseudo-first-order rate constants ( $k_{\text{obs}}$ ) vs concentrations of  $\text{Fc}^*$  in the first electron transfer from  $\text{Fc}^*$  to  $[\text{Cu}^{\text{II}}_2(\text{LO})(\text{OH})]$  (**D1**) (0.10 mM) to determine the  $k_{\text{et}1}$  value in the presence of HOTF (2.0 mM) in acetone at 203 K.

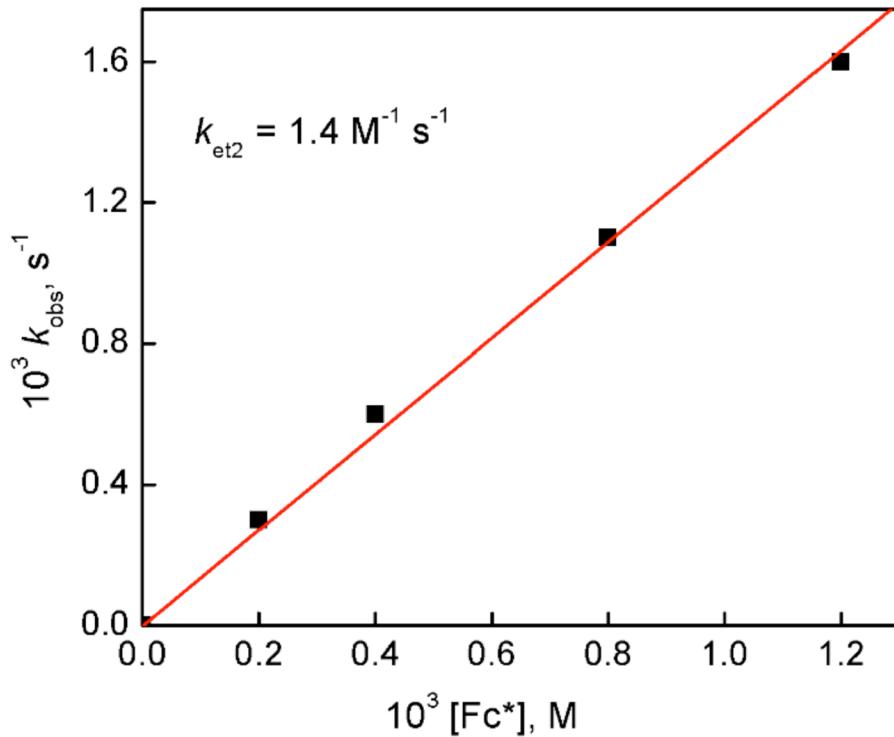

**Figure 7.**

UV-vis spectral changes observed in the electron transfer from  $\text{Fc}^*$  (1.2 mM) to  $[\text{Cu}^{\text{II}}\text{Cu}^{\text{I}}(\text{LO})]^{2+}$  (**D2**) (0.10 mM), formed as described in the text, in the presence of HOTF (2.0 mM) at 213 K. The Inset shows the time profile of the absorbance at 780 nm due to  $\text{Fc}^{*+}$ . Note: the nonzero absorbance at 780 nm before the mixing of **D2** and  $\text{Fc}^*$  is due to a *d-d* transition of this complex and this causes a large increase in recording of the first spectrum. For practical reasons this absorbance is subtracted from the total absorbance to give the absorbance due to  $\text{Fc}^{*+}$  to calculate the rate constant.

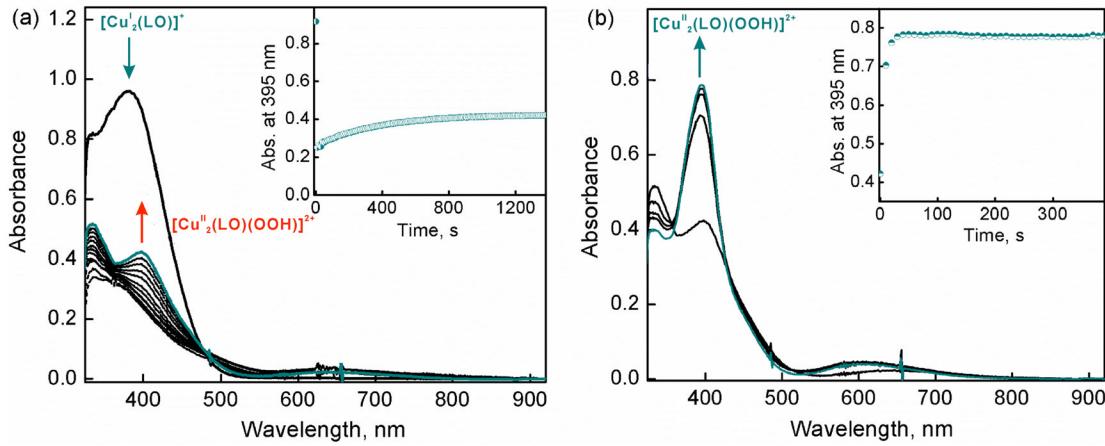

**Figure 8.**

EPR spectrum of  $[\text{Cu}^{\text{II}}\text{Cu}^{\text{I}}(\text{LO})]^{2+}$  (**D2**) (1.0 mM) recorded in acetone at 5 K. **D2** was generated in the reaction of **D1** (1.0 mM) and  $\text{Fc}^*$  (1.0 mM) in the presence of HOTF (5.0 mM) in acetone at 298 K. The experimental parameters: microwave frequency = 9.6483 GHz, microwave power = 1.0 mW, and modulation frequency = 100 kHz.

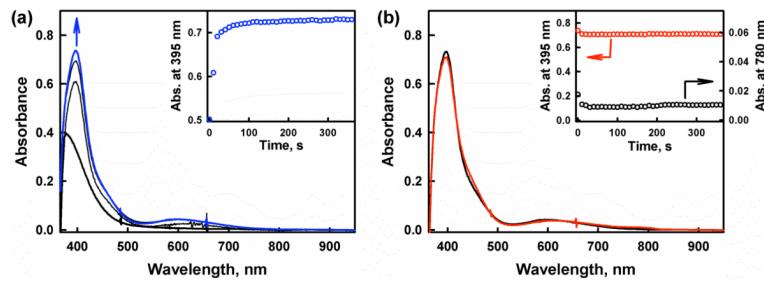

**Figure 9.**

Plot of the pseudo-first-order rate constants ( $k_{\text{obs}}$ ) vs concentrations of  $\text{Fc}^*$  in the second electron transfer from  $\text{Fc}^*$  to  $[\text{Cu}^{\text{II}}\text{Cu}^{\text{I}}(\text{LO})]^{2+}$  (**D2**) (0.10 mM) to determine the  $k_{\text{et2}}$  value in the presence of HOTF (2.0 mM) in acetone at 213 K.

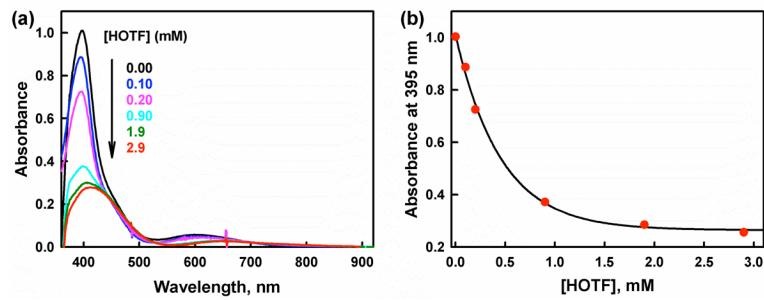

**Figure 10.**

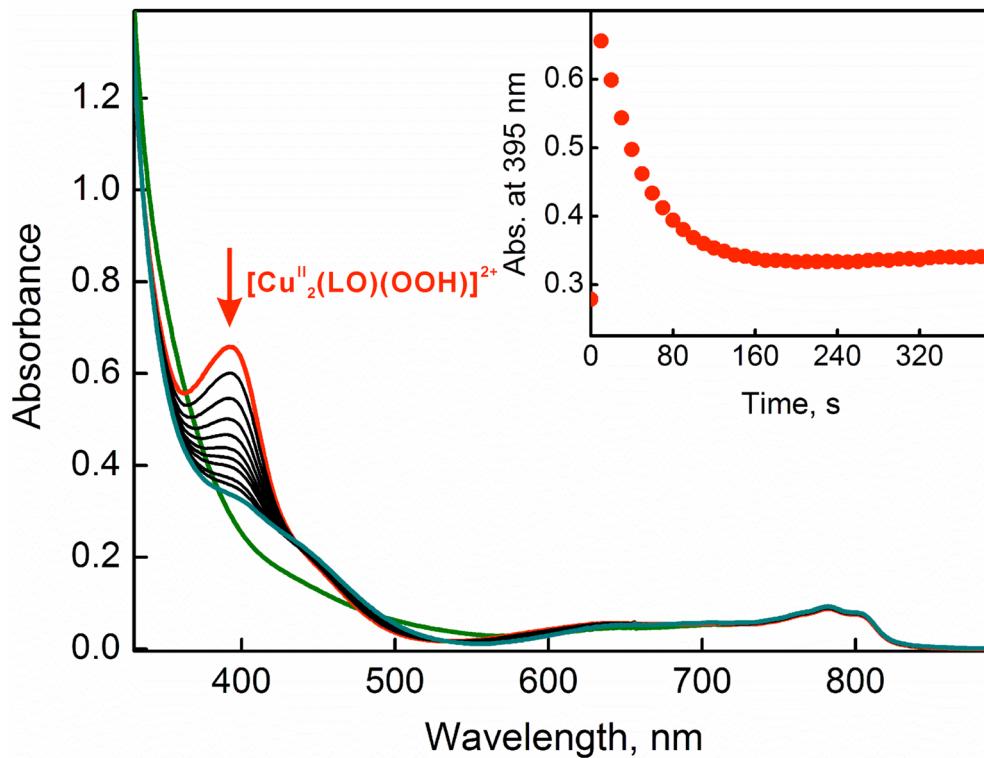

UV-vis spectral changes and time profiles of (a)  $[\text{Cu}^{\text{I}}_2(\text{LO})]^+$  (**D3**) (0.070 mM) after  $\text{O}_2$  introduction demonstrating the generation of  $[\text{Cu}^{\text{II}}_2(\text{LO})(\text{OOH})]^{2+}$  (**D4**) at 395 nm and (b) **D3** (0.070 mM) after  $\text{O}_2$  introduction and addition of 1 equiv HOTF (0.070 mM) in acetone at 193 K.

**Figure 11.**

(a) Full formation of the  $[\text{Cu}^{\text{II}}_2(\text{LO})(\text{OOH})]^{2+}$  (**D4**) in an acetone solution containing  $[\text{Cu}^{\text{I}}_2(\text{LO})]^+$  (**D3**) (0.070 mM) and HOTF (0.070 mM) after  $\text{O}_2$  introduction at 193 K. Inset shows the absorbance change at 395 nm due to the generated hydroperoxo species. (b) Addition of excess  $\text{Fc}^*$  (0.28 mM) (red spectrum) to the hydroperoxo species generated (black spectrum) in acetone at 193 K.

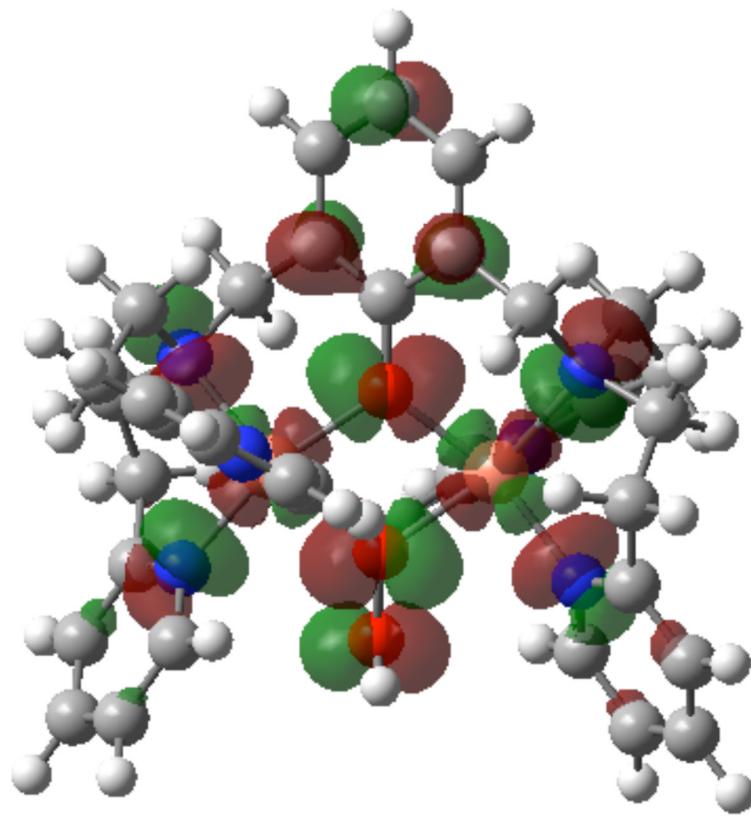

**Figure 12.**

(a) UV-visible spectral changes of  $[\text{Cu}^{\text{II}}_2(\text{LO})(\text{OOH})]^{2+}$  (**D4**) (0.10 mM) in the presence of HOTF (0.10 – 3.0 mM) in acetone at 193 K. (b) Absorbance changes at 395 nm as a function of HOTF concentration.

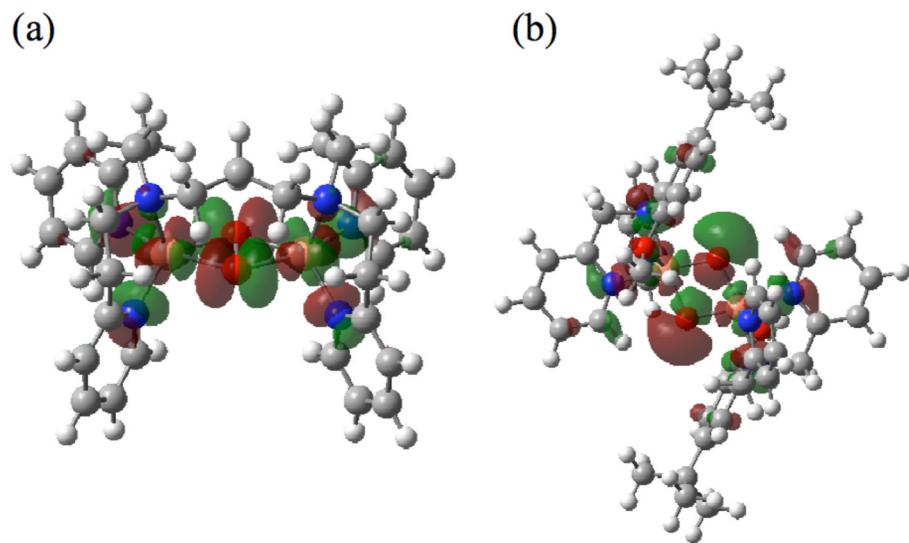

**Figure 13.**

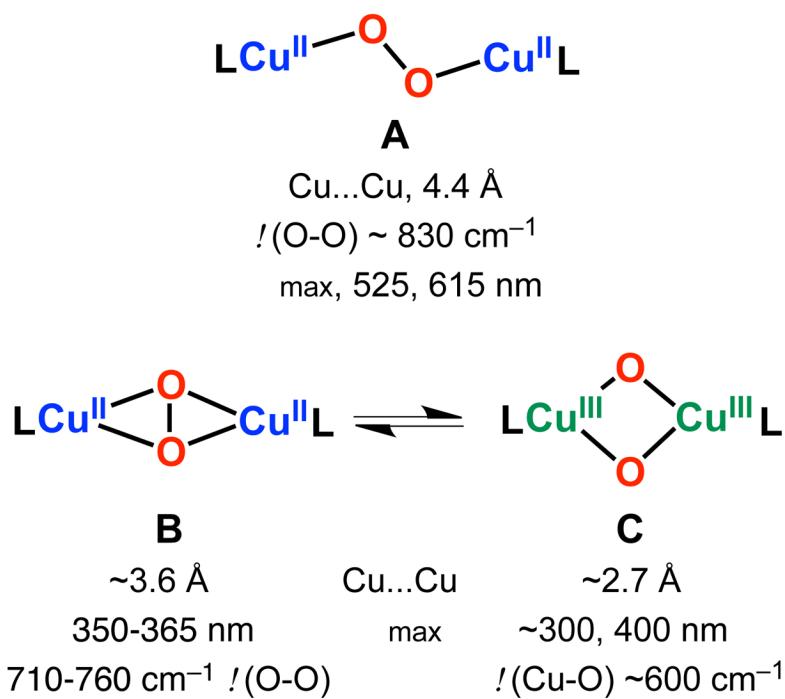

(a) UV-visible spectral changes resulted from introduction of O<sub>2</sub> at 193 K into an acetone solution of  $[\text{Cu}^{\text{II}}\text{Cu}^{\text{I}}(\text{LO})]^{2+}$  (**D2**) (green spectrum) produced from room temperature mixing of  $[\text{Cu}^{\text{II}}_2(\text{LO})(\text{OH})]$  (**D1**) (0.10 mM) and Fc\* (0.10 mM) in the presence of HOTF (1.0 mM). The Inset shows the time profile of the absorbance at 395 nm due to the  $[\text{Cu}^{\text{II}}_2(\text{LO})(\text{OOH})]^{2+}$  (**D4**) generated (red spectrum).

**Figure 14.**

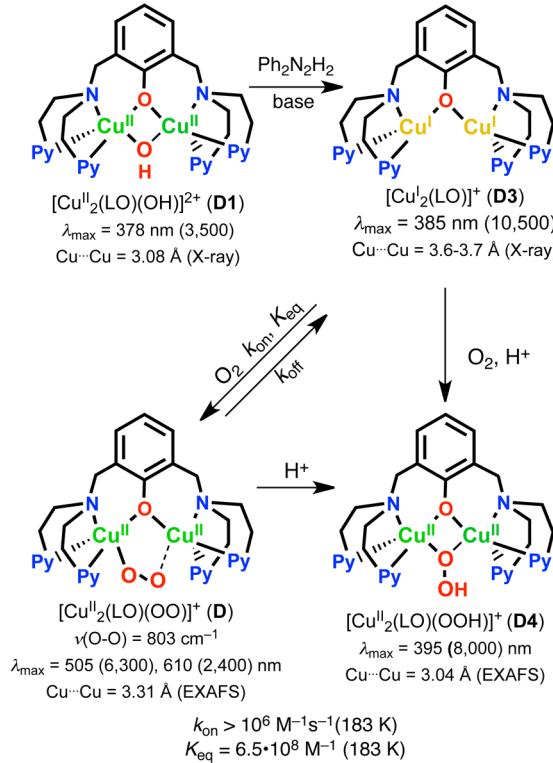

Optimized structure with LUMO orbital of  $[\text{Cu}^{\text{II}}_2(\text{LO})(\text{OOH})]^{2+}$  (**D4**) calculated by DFT B3LYP/lanl2dz basis set.

**Figure 15.**

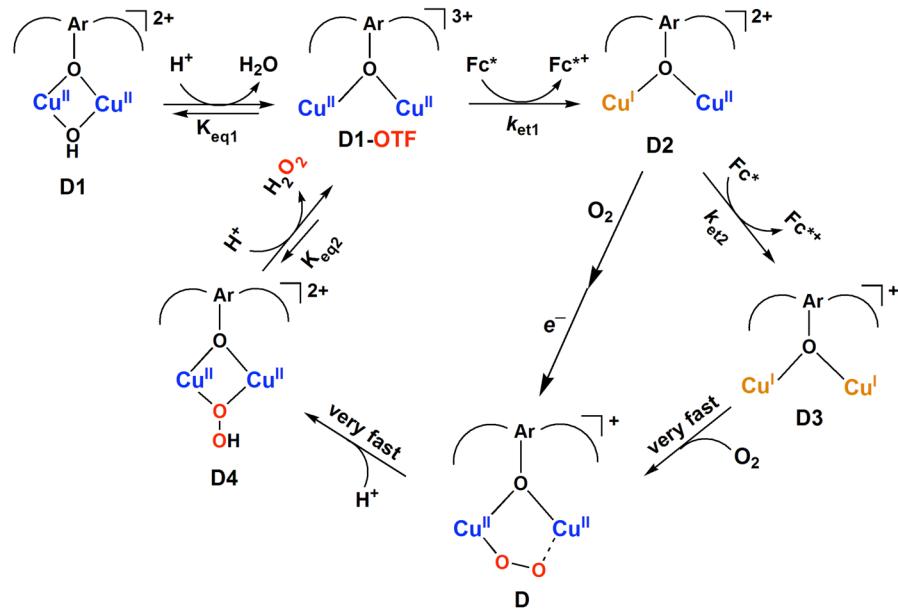

Optimized structures with LUMO of (a)  $[\text{Cu}^{\text{II}}_2(\text{N}_3)(\text{O}_2)]^{2+}$  calculated and (b)  $[(\text{BzPY1})\text{Cu}^{\text{III}}(\text{BzPY1})(\text{O})_2\text{Cu}^{\text{III}}(\text{BzPY1})]^{2+}$  by DFT B3LYP/Lanl2dz.

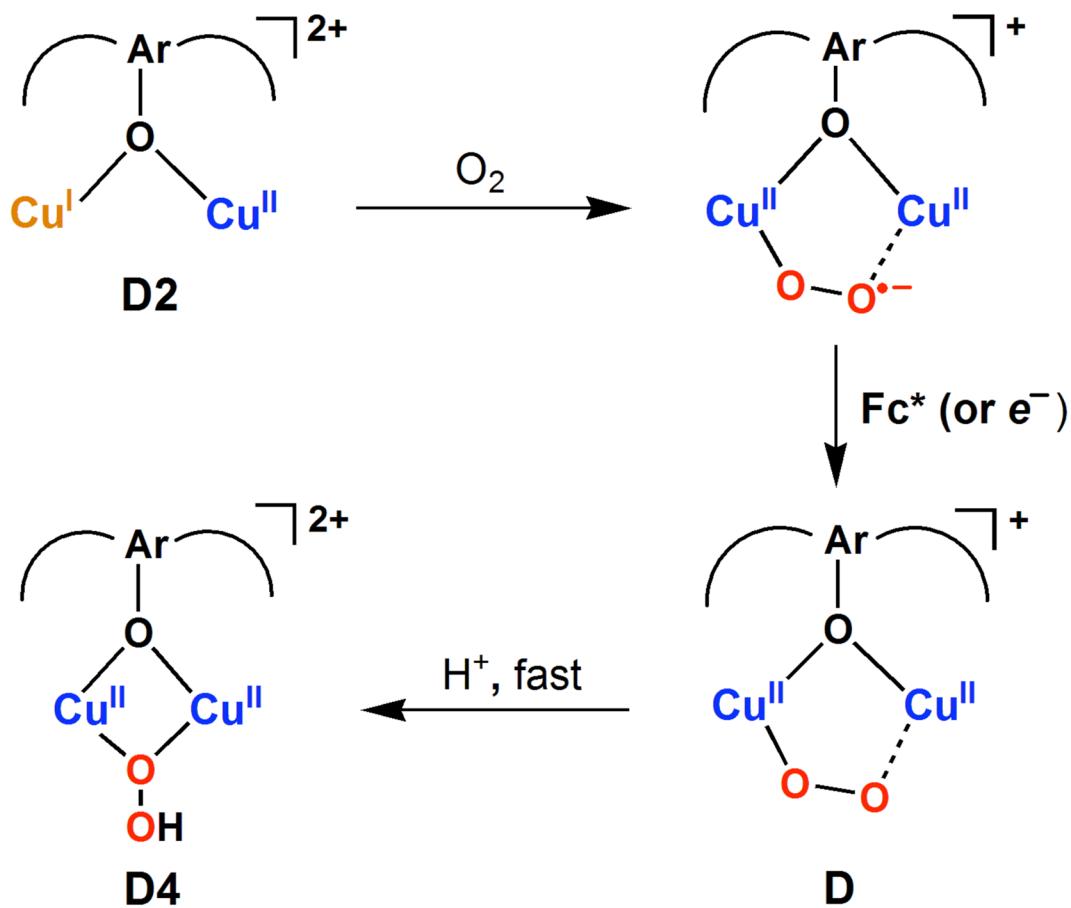

Scheme 1.

Scheme 2.

**Scheme 3.**

Reaction sequence deduced for the catalytic two-electron two-proton reduction of  $O_2$  to  $H_2O_2$ . The initial catalyst is  $[Cu^{II}_2(LO)(OH)](SbF_6)_2$  (**D1**) and the reaction is carried out in acetone solution using decamethylferrocene ( $Fc^*$ ) as reductant and trifluoroacetic acid (HOTF) as proton source. See text for further details, including the “short-circuit” path from **D2** to **D**.

Scheme 4.
