intensities depend much on the history of the preparation of the samples. The most reproducible form of  $\gamma$ -Al<sub>2</sub>O<sub>3</sub>, as judged by X-ray and electron diffraction, was obtained by oxidizing in air thin films of aluminum at about 800°. Similar calculations as for  $\gamma$ -Cr<sub>2</sub>O<sub>3</sub> were made for this case and the calculated intensity values are set out in Table IV together with the observed values.

The absence of the 111 reflection is significant and almost rules out the possibility of vacancies in tetrahedral positions. There is a fair over-all agreement between the experimental intensities and those calculated on the assumption of the vacancies predominating at octahedral sites. This may indicate a random distribution of vacancies at octahedral positions. Certainly, the possibility of a statistical vacancy distribution both at octahedral and tetrahedral positions cannot be ruled out in the light of the existing data. However, in view of the known distribution in other defect spinels the tentative formula  $Al^{3+}[Al^{3+}]_{-1} \square_{/2} O_{2}^{2-}$  may be assigned to  $\gamma$ - $Al_{2}O_{3}$ .

## Conclusion

X-Ray, electron diffraction and magnetic data for defect spinel type oxides indicate that the cation vacancies predominate among the octahedral positions. In  $\gamma\text{-Fe}_2\mathrm{O}_3$  there is an ordered distribution of the vacancies at octahedral sites probably around the cell center. In  $\gamma\text{-Mn}_2\mathrm{O}_3$ ,  $\gamma\text{-Cr}_2\mathrm{O}_3$  and  $\gamma\text{-Al}_2\mathrm{O}_3$  the vacancies are randomly distributed among the octahedral positions and an ordered superstructure of vacancies is apparently lacking in these oxides.

The tetragonal symmetry of  $\gamma$ -Mn<sub>2</sub>O<sub>3</sub> and Mn<sub>3</sub>O<sub>4</sub> is to be attributed to the ability of Mn<sup>3+</sup> ions at octahedral sites to form dsp<sup>2</sup> empty hybrid square bonds with the overlapping oxygen orbitals, the tetragonal structure being further stabilized as a result of the formation by the Mn<sup>3+</sup> and Mn<sup>2+</sup> ions of d<sup>2</sup>sp irregular tetrahedral bonds at tetrahedral positions. The ideal axial ratio of c/a = 1.16 seems to be attained when both these bonding mechanisms are operative.

## HEAT CAPACITIES AT LOW TEMPERATURES, ENTROPY AND ENTHALPY INCREMENTS OF FOUR NICKEL-ZINC FERROSPINELS<sup>1</sup>

By Edgar F. Westrum, Jr., and D. M. Grimes

Contribution from the Departments of Chemistry and of Electrical Engineering of the University of Michigan, Ann Arbor, Michigan

Received December 18, 1956

Heat capacities from 5° to above 300°K, were determined on synthetic samples of  $Ni_{1-x}Zn_xFe_2O_4$  with x=0.6, 0.7, 0.8 and 0.9 to test a hypothesis of Yafet and Kittel concerning triangular transformations. The normal sigmoid dependence of heat capacity on temperature is modified by ferrimagnetic contributions, and an antiferromagnetic transformation near 10°K, becomes increasingly more pronounced with increasing zinc content. Thermodynamic functions have been evaluated from the data presented.

Spinel minerals are fairly common and include important ores. Synthetic ferrospinels (ferrites) possess interesting electromagnetic properties and are technologically significant components of high frequency electrical circuits. Despite these facts, thermal data extending to liquid helium temperatures (and thereby permitting a more accurate eval-

(1) Presented at the Ninth Annual Calorimetry Conference in Schenectady, New York, on September 18, 1954. This work was supported by the U. S. Army Signal Corps through the Engineering Research Institute of the University of Michigan.

uation of the thermodynamic properties) are available probably only for zinc ferrite (ZnFe<sub>2</sub>O<sub>4</sub>).<sup>2</sup> Heat capacity data above 50°K. have, however, been published for more than twelve others,<sup>3</sup> and measurements on magnetite over the range 1.8 to 4.2°K. recently have been published.<sup>4</sup>

The gross magnetic properties of the ferrospinels have been explained by Néel<sup>5</sup> in terms of the parallel and antiparallel alignment of the magnetic moments of the ions on two sublattices. For instance, in nickel ferrite (NiFe<sub>2</sub>O<sub>4</sub>), the antiferromagnetic interaction between the moments of the two sublattices gives rise to ferrimagnetism at 0°: however, in zinc ferrite (ZnFe<sub>2</sub>O<sub>4</sub>), the net spin of the zinc ion is zero and the iron atoms are paramagnetic at this temperature. Mixed nickel-zinc ferrites are ferrimagnetic with a magnetic moment increasing with nickel content over the range studied. For certain ratios of inter- to intra-sublattice interactions, it is anticipated by Yafet and Kittel<sup>6</sup> that the moments of two sub-sublattices composing one of the sublattices will be oriented neither parallel nor antiparallel with each other, but at some intermediate angle. The existence of such a triangular configuration would give rise to the possibility of transitions between triangular and ferrimagnetic or antiferromagnetic states and hence to singularities analogous to Curie and Néel points. Utilizing an experimental evaluation of the exchange interactions by Néel and Brochet for mixed nickel-zinc ferrites  $(Ni_{1-x}Zn_xFe_2O_4)$ , Yafet and Kittel<sup>6</sup> predicted the possible existence of such multiple transitions in mixed nickel-zinc ferrites with x > 0.7.

Such transitions should be detected readily at low temperatures by precise heat capacity determinations, for the discontinuities associated with the various types of transitions are well within the range of measurement of modern adiabatic, cryogenic calorimetry. The thermal method has the advantage of avoiding the spurious effects in magnetic measurements occasioned by ferromagnetic impurities. To test the theory of Yafet and Kittel, determination of the heat capacity of Ferramic E, a commercially available ferrite with x approximating 0.6, was first measured. Although no evidence of the anticipated spectrum of transformations was observed, the composition was indeed outside the range specified by Yafet and Kittel.<sup>6</sup> A ferrite of composition x = 0.8 was then fabricated and its heat capacity determined. An anomalously high heat capacity in the vicinity of 10°K. provoked further measurements on additional samples over the range  $0.6 \le x \le 1.0$ . In conjunction with neutron diffraction data<sup>8</sup> it has been established that this anomaly arises as a consequence of the antiferromagnetic-paramagnetic transition in pure zinc ferrite.<sup>2</sup> Although resolution of the magnetic and lattice components of the heat capacity is not yet possible, the thermodynamic data are presented as a contribution to the thermodynamics of solid solutions.

Preparation and Purity of Samples.—Mixed nickel-zine ferrites, the composition of which may be represented by the empirical formula  $Ni_{1-x}Zn_xFe_2O_4$  with x=0.6,0.7,0.8and 0.9, were prepared by milling a slurry of weighed quantities of chemically pure oxides in a steel ball mill for six hours. After drying, the mixture was pressed into 50-g. slugs and fired at 1200° for four hours in air and the temperature then reduced 60°/hr. to about 400° in an oxygen atmosphere.

and the second of the second o

The slugs were fragmented in a hardened-steel "diamond annealed in an oxygen atmosphere and cooled at a rate of 60°/hr.

Because of the strong dependence of the heat capacity in the vicinity of 10°K. upon composition as x approaches unity, especially great care was taken in the preparation technique to obtain a stoichiometric, homogeneous, noninverted sample of zinc ferrite. The details of the fabrication procedure utilized are described elsewhere.2 Gravimetric chemical analyses for iron and zinc and spectrochemical analyses were made. Stannous chloride oxidation-reduction titrations were made to determine the ferrous iron content of the samples. X-Ray diffraction photographs were taken to establish the phase purity of the samples. The analytical data are presented in Table I.

<sup>a</sup> Ferramic E, General Ceramic and Steatite Corp. <sup>b</sup> Per cent. zinc found =  $27.2 \pm 0.1$  (theoretical, 27.12).

Cryogenic Technique.—The design and adiabatic method of operation of the Mark I cryostat9 and calorimeters W-510 and W-911 have been described. A calorimeter was in turn loaded with sample, evacuated and 2 to 4 cm. of gaseous helium added at 25° to aid in the establishment of thermal equilibrium. Lubriseal stopcock grease was used on cal-orimeter W-5 for thermal contact between heater, thermometer and calorimeter for determinations on samples with x = 0.6 and 0.8 and on Ferramic E. Calorimeter W-9 with Apiezon T grease was employed for the balance of the runs to allow measurement to 350°K. Separate determinations of the heat capacity of the empty calorimeters were made with their respective conductivity greases. The made with their respective conductivity greases. The following masses (vacuo) of samples were employed in the measurements: x = 0.6, 203.434 g.; x = 0.7, 164.515 g.; x = 0.8, 191.862 g.; x = 0.9, 180.265 g.

Temperatures were determined with a capsule-type platinum resistance thermometer (Laboratory Designation A-3) contained in a central well in the calorimeter. It was calibrated by the National Bursey of Standards from 10.

contained in a central well in the calorimeter. It was calibrated by the National Bureau of Standards from 10 to above 373°K. Below this temperature range a provisional scale was employed. It is considered that the thermometer reproduces the thermodynamic temperature scale within 0.1° from 4 to 10°K., within 0.03° from 10 to 90°K., and within 0.05° above 90°K. The ice point was taken as  $\frac{372.16\%}{10.0000}$  Collibrated instruments were used in the de-273.16°K. Calibrated instruments were used in the determination of all the measured quantities including the

timing of the energy input.

Heat Capacity Results.—The experimental heat capacity determinations for the four samples of ferrospinels synthesized in this Laboratory are presented in Table II in chronological sequence so that the temperature increments of the individual runs can be inferred from the adjacent mean temperatures. Corrections for curvature (occasioned by the finite temperature increments employed in the measurements) and for the slight differences in the amounts of heium and solder in the measurements on the empty and the full calorimeters have been applied. The data are presented in terms of the defined thermochemical calories of 4.1840 absolute joules and the formula (molal) weight in grams using 1953 International Atomic Weights.

Heat capacities below 50°K. are presented in Fig. 1. Figure 2 compares the heat capacities at higher temperatures with the smooth curve for zinc ferrite2 in order to amplify the small differences between these curves.

plots the points indicated represent the individual determinations, and the heat capacities of Ferramic E and zinc ferrite<sup>2</sup> have been included for comparison. The significant features are: (1) the sharp antiferromagnetic-paramagnetic transition in zinc ferrite at about 9.7°K, which obviously persists in the mixed ferrospinels at approximately the same temperature, but decreases in intensity with increasing nickel content; and (2) the absence of other peaks or fluctua-tions in the curves. No singularities of the type predicted by Yafet and Kittel<sup>§</sup> were observed. The ferrimagnetic contributions to the thermal properties cannot at present be quantitatively resolved from those of the lattice

Thermodynamic Functions.—The entropies and enthalpy increments computed by numerical quadrature from large scale plots of the heat capacity are provided at selected temperatures in Table III. Nuclear spin and isotope mixing contributions have not been included in the entropy. Extrapolation below about 5°K. was made with the Debye limiting law. The estimated probable error in the entropy increment is  $\pm 0.06$  e.u. and that in the enthalpy increment is  $\pm 0.1\%$ . More extensive tabulation of the temperature dependence of the thermodynamic functions of these four ferrites have been prepared. 12

(12) Extensive tabulation of the heat capacities, enthalpy and entropy increments and enthalpy function of these four ferrospinels in addition to heat capacity data on Ferramic E have been deposited as Document Number 5113 with the ADI Auxiliary Publications

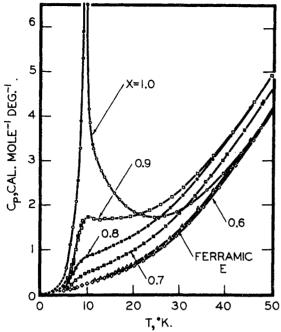

Fig. 1.—Molal heat capacity vs. temperature for six samples of Ni<sub>1-x</sub>Zn<sub>x</sub>Fe<sub>2</sub>O<sub>4</sub> compositions below 50°K.

If the nickel ions occupy B sites and zinc ions occupy A sites, then the configurational entropy resulting from mixing zinc and iron ions at random on the A sites is given by

$$S_A = -R \ln [x^x (1-x)^{1-x}]$$

and the configurational entropy resulting from mixing zinc and iron ions at random on the B sites is given by

$$S_{\rm B} = -R \ln \left[ 4^{-1} (1-x)^{1-x} (1+x)^{1+x} \right]$$

The sum of these two expressions represents an upper bound to the zero-point entropy and amounts to 0.72R, 1.15R, 1.46R and 1.67R for x=0.9, 0.8, 0.7 and 0.6, respectively. The actual entropy at  $0^{\circ}$ K. will be less than the above due to the mutual ordering effects of the A and B sublattices by the electrical interactions between them.

Acknowledgment.—The authors express their appreciation to Prof. H. W. Welch, Jr., for his interest in this problem, to Clinton Jefferson and J. W. Kuiper for their preparation of the calorimetric samples and some of the analytical studies,
